## Report No 1/1967

AN ANALYSIS OF SOME BACKGROUND FACTORS AFFECTING THE RECRUITMENT AND ACHIEVEMENT OF STUDENTS ENROLLED FOR EXAMEN ARTIUM IN NORWAY

By SIGMUND VANGSNES

# AN ANALYSIS OF SOME BACKGROUND FACTORS AFFECTING THE RECRUITMENT AND ACHIEVEMENT OF STUDENTS ENROLLED FOR EXAMEN ARTIUM IN NORWAY 

This report presents some findings from a statistical/sociological investigation of students leaving the Gymnas in Norway. The Norwegian Gymnas is a secondary school where the students work towards the examen artium, the passing of which is a prerequisite to admission to a university. This investigation includes all students who entered for this examination in the years 1946, 1951, 1958 and 1963 and describes the composition of this group according to course of study, final grades and such factors as age, sex, and social and regional background. It also shows how these factors affect both a student's chance of attending a Gymnas and his subsequent school achievement. The report also gives a historical review of all those who graduated from the Gymnas for the period 1900-1965, with some details about the composition of this group with regard to sex and course of study.

A follow-up study in a later report will show the subsequent career pattern of these pupils both at the university and in other forms of post-secondary education, and the relation between this pattern and the factors mentioned above.

The primary data in this document are collected from the Central Bureau of Statistics and the Gymnasråd (the official body responsible for the administration of the Gymnas - under the Ministry of Church and Education). The research work was directed by Sigmund Vangsnes, who has prepared this report in co-operation with Kaare Andersen.

## Findings:

1. At the beginning of the century the graduate incidence ${ }^{x}$ ) was $1 \%$. In 1920 it was about $2 \%$, and at the beginning of World War II about
x) The usual age at graduation from the Gymnas is now $19 \frac{1}{2}$ years, but from 1900 to 1943 it was $20 \frac{1}{2}$ years. The term "graduate incidence" is used in this report to denote the proportion of Gymnas graduates to the total population having the same age as the graduates.
$5 \%$. This percentage rose considerably during the Second World
 years) graduated. After a 12-year stagnation period, the graduate incidence again began to increase rapidly, and in 1965 reached 17 \% ( 18 \% if we include the Economic Gymnas, a new secondary school, whose first students graduated in 1953).
2. In 190010 \% of graduates from the Gymnas were girls. The percentage rose rapidly until 1915, when it reached $30 \%$. Since then the increase has been very gradual. In $194540 \%$ of Gymnas graduates were girls, and in 1965 about $43 \%$.

In 196525 \% of the girls chose a Science course and $75 \%$ an Arts course, while $70 \%$ of the boys chose a Science course and $30 \%$ an Arts course. The girls' preference has been comparatively stable throughout the past 25 years, but the boys have shown a steady increase in their preference for Science courses during this period.
3. With regard to regional origin of Gymnas graduates the proportions have changed very little in the post-War period. Although the number of Gymnas graduates and the graduate incidence increased considerably in the years from 1960, in 1963 the proportion of graduates from the Oslofjord region to those from the Northern region was still more than 2:1-as had been the case in 1946. The explosive increase in graduate incidence in the beginning to the 60's has only to a small extent altered the regional distribution of Gymnas graduates.
4. From the end of the 40's to the end of the 50's there was little variation in number and social composition of Gymnas graduates. Since 1958, on the other hand, there has been a large increase in the number as well as a considerable variation in the social composition of the graduates.

In the 1950's only 13-14 \% of Gymnas graduates were the children of manual workers, but in 1963 this figure had risen to $18.5 \%$. From 1958 until 1963 the graduate incidence increased in all
social groups, but to a greater degree in the following groups: Manual workers, foremen, and craftsmen.

Although there has been considerable rise in the graduate incidence in these under-represented social groups in recent years, the social composition of Gymnas graduates is still very uneven. In 1963 the graduate incidence of the social group "Managerials and professionals" was over $50 \%$, whilst in the group "Manual workers and foremen" it was less than 10 \%.
5. The findings in this report indicate that there is a clear relationship between the economic and social structure in a region and the graduate incidence in that region. The regional differences in graduate incidence seem to a great extent to be related to differences in the social composition of the population of the region and have a tendency to disappear if the social class factor is kept constant. In 1963 the graduate incidence for "Manual workers and foremen" was about 7-8 \% in all six regions of Norway, and was furthermore the same in the industrialized Oslofjord region as in the less developed Northern region, and the same in urban regions as in regions with a lower population density.

For "Clerical workers", also a relatively homogenous group, the graduate incidence varied from 27 \% in the Oslofjord region to 23 \% in the Northern and Western regions. For the other social groups which are much more heterogenous as regards income and social status, geographical variation in graduate incidence is greater. This can to a certain extent be explained as an effect of regional differences on the internal composition of the groups.
6. The percentage of good grades (S and M) has risen in the post-War period. The improvement in grades has taken place in both sexes, but the percentage of good grades is slightly higher among boys than among girls. It is also higher among Science graduates than among Arts graduates.

The number of good grades is relatively higher in the economically less developed regions than in the central urbanized regions - the percentage of good grades was highest in the regions with lowest graduate incidence.

The tables and graphs in this English summary are numbered after those in the report in Norwegian.

Figure 3 II. Gymnas graduate incidence ${ }^{x}$ ) in the years 19001965.

x)

The term "graduate incidence" is used in this report to denote the proportion of Gymnas graduates to the total population having the same age as the graduates.
